

## Evolution of Teachers' Salaries in Latin America at the turn of the 20<sup>th</sup> century

How much are they (under or over) paid?

Alejandra Mizala and Hugo Ñopo \*

### Abstract

How much are teachers paid in comparison to those in other professions in Latin America? How have these differences evolved at the turn of the 20th century? This paper reports the evolution, between circa 1997 and circa 2007, of teachers' salaries vis-à-vis workers in other professional and technical occupations for thirteen Latin-American countries. After controlling the earnings differentials by observable characteristics linked to productivity it is found that the hourly earnings gap, although substantial, decreased throughout the decade. This has been the case for hourly earnings gaps at the main and secondary jobs. Most of the drop in earnings gaps is attributed to a general trend in gap reduction rather than as a result of teachers' improvements on their observable characteristics. The earnings gap shows heterogeneities, across countries and along the earnings distributions.

JEL classification: I2, J31, J44, J8, O54.

Keywords: education, wage differentials, professional labor markets, national and international labor standards, Latin America, Caribbean.

## 1. Introduction

School teachers' salaries are often perceived to be lower than those of other professionals; this perception is especially strong among teachers. This affects the teachers' motivation to educate (OECD 2009; Figlio and Kenny 2006; Ortega 2010, Player 2009, Heutel 2009, Loeb and Page, 2000); causes good teachers to leave the profession (Imazeki 2005; Harris and Adams, 2007; Scafidi et al., 2007); and good students to avoid choosing an education major in college. These in turn would produce negative effects in students' learning. To improve the quality of education it is essential to pay special attention to teachers (Clotfelter et al. 2007; Kukla-Acevedo 2009), and to implement policies to attract, motivate and retain the most talented individuals in the profession.

A series of studies have analyzed teachers' salaries, with mixed results regarding their relative under or over-payment in the labor markets. In fact, the available empirical evidence shows that the sign and the magnitude of the conditional wage differential between teachers and other workers crucially depends on the definition of the comparison group, even when differences in observable characteristics are accounted for, both in Latin America<sup>1</sup> and out of the region<sup>2</sup>.

More recently Mizala and Ñopo (2011), analyzing representative samples of nine Latin American countries circa 2007, found that teachers' underpayment is stronger than what has been previously reported in the literature for Latin America. Teachers' underpayment with respect to other professionals and technicians was found to be more pronounced among males, older workers, household heads, part-timers, formal workers, those who work in the private sector, and (mostly) among those with complete tertiary education. Exploring the role of job schedules and

---

<sup>1</sup> Psacharopoulos et al. (1996), Liang (1999), and Hernani-Limarino (2005) analyze several Latin American countries. Saavedra (2004) examines Perú; Mizala and Romaguera (2005) Chile; Lopez-Acevedo and Salinas (2004) Mexico; Rivas and Lavarreda (2008) Guatemala; Herrero et al. (2003) Argentina; Piras and Savedoff (1998), Urquiola et al. (2000) and Urquiola and Vegas (2005) Bolivia.

<sup>2</sup> Taylor (2008), Allegretto et al (2008), Podgursky and Tongrut (2006), Harris and Adams (2007), Stoddard (2005) for United States, Asadullah (2006) for Bangladesh; Komenan and Grootaert (1990) for Cote D' Ivoire; Zymelman and DeStephano (1989) for Sub-Saharan African countries.

job tenure (which are claimed to be more flexible and longer, respectively, for teachers) as compensating differentials, it was found that even after accounting for them the conditional earnings gap prevails. This paper builds up on these results, expanding them in three important dimensions: (i) exploring the evolution of those conditional earning gaps between circa 1997 and circa 2007, (ii) expanding the number of countries to thirteen, improving on its representativeness, and (iii) exploring deeper into the role of individuals' unobservable characteristics by using information from their main and second jobs.

The question of earnings differentials conditioning on observable characteristics is assessed with a non-parametric matching approach developed in Nopo (2008). The results depict a picture in which teachers are underpaid vis-à-vis other professionals and technicians. We found, however, that preschool and elementary teachers' earnings (vis-à-vis those of other professionals and technicians) improved during the decade, especially for the young, females, part-time workers and those holding only one job. It is found that this improvement responds to a general trend of earnings gaps decreasing in the segments considered of the labor market, which offsets an increase in the earnings gap due to changes in the distribution of individuals' observable characteristics.

Also, teachers more frequently report having more than one job compared to other professionals and technicians. Then, analyzing earnings gaps at main and secondary jobs we find that these prevail in both. This suggests the existence of some sort of unobservable individuals' (job-independent) traits that make teachers underpaid. This issue may in turn call to attention of possible selection mechanisms of lower ability individuals into the teaching profession.

The rest of the paper proceeds as follows. In the next section we introduce the data sources, the approach to harmonize them across countries and some descriptive statistics comparing

teachers with other professionals and technicians. In section three we present the main empirical analysis of earnings gaps decompositions, analyzing its evolution during the 10-year period, and exploring the role of some amenities of the teaching profession: shorter and more flexible job schedules (with the consequent possibility of holding an extra job and enjoying extra vacation periods), and more job stability (distinguishing it between the private and public sectors). In the fourth section we summarize and conclude.

## **2. The Data**

The data comes from nationally representative household and labor surveys of thirteen Latin-American countries circa 1997 and circa 2007. Table A1 (see the on-line Appendix) reports the specifics of each data source: the country, the survey name, the year and the number of observations for the whole sample of workers (“Full Set”) and the subsamples of workers that will be compared (“Pre-School and Elementary Teachers”, “High School Teachers” and “Other Professionals and Technicians”). The expansion factors of each data set are used such that the relative size of each sample proportionally corresponds to the working population of each country. Table A2 in the on-line Appendix shows the occupational categories that we used in each country to identify teachers and other professionals and technicians. University teachers and those with particular specialties (e.g., teachers for students with special needs, language instructors, sports instructors, driving instructors, and dance or art instructors) are not considered for the analysis. They are neither part of the teachers’ nor of the non-teachers’ population. Then, when we refer here to teachers or school teachers, we will be referring to both high school teachers and pre-school and elementary teachers.

The sample of interest (school teachers and other professionals and technicians) represents 10.2% and 14.4% of the working sample circa 1997 and circa 2007, respectively. Those who declare being teachers stand for 3.5% and 3.1%, and the other professionals and technicians stand for 6.6% and 11.3% of the working sample for each period, respectively. Outliers for income at the main occupation were dropped from the data set. This comprised 1% of the working sample for both periods under analysis (0.3% and 0.6% percent of the school teachers, and 6% and 5% percent of the other professionals and technicians for each period, respectively).

Table A1 shows that the proportion of teachers ranges from 2% to 5% in both periods and it slightly decreased for many countries: Bolivia, Brazil, Chile, El Salvador, Panama, Paraguay and Peru. On the other hand, the population of other professionals and technicians increased for all countries during the period.

The available empirical evidence shows that the sign and magnitude of the conditional earnings differential between teachers and other workers crucially depend on the definition of the comparison group. Hernani-Limarino (2005) shows an increase in the unconditional earnings differentials in favor of teachers when these are compared with workers with lower productive endowments. On that regard, it is important to highlight that our comparison group differs from those reported in the literature. We compare teachers to other professionals and technicians, aiming at comparing workers with similar or comparable skills. Table 1 contrasts our results for pre-school, elementary and high school teachers with those that the three regional pieces of the literature would deliver for the uncontrolled earnings gap using our data set and their definition of teachers and comparison groups. The previous literature have included Legislators, Managers, Armed forces and, especially, Office workers as part of the comparison groups understating the magnitude of the earnings gaps.

Table 2 shows the descriptive statistics for observable characteristics in all countries' data sets for the two periods of analysis. Teaching is a predominantly female occupation as approximately nine out of ten pre-school and elementary teachers are women, and six out of ten high school teachers are so. On the other hand, the proportion of males among other professionals and technicians is roughly more than 50%. Such compositions remain almost unchanged over the decade. The working population aged during the period. Workers above 45 years old increased their share in all comparison groups but this has been more pronounced in the case of teachers.

Pre-school and elementary school teachers became more professionalized during the decade as the percentage of those with tertiary complete education jumped from 13% to 19%. This did not happen among neither high-school teachers nor other professionals and technicians. In all comparison groups the share of workers with secondary education increased while the share of those with lower education decreased. Teachers' educational achievement surpasses that of other professionals and technicians and this has not changed during the decade.

In both periods around 50% of pre-school and elementary teachers report living with children (12 years old or younger), while around 45% of high school teachers and non-teachers do so. The trend during the decade, however, shows a decrease in fertility in all workers' households. Also teachers, particularly high school teachers, report living with elder people (65 years or older) in a higher proportion than the other groups. Household headship has been less prevalent among teachers than among other professionals and technicians, but increased for the former during the decade. Similarly, presence of other household member generating labor income, another proxy for financial responsibility, reveals the shortening of differences between teachers and other professionals and technicians. The proportion of teachers working part-time (30 hours or less per week), although has declined, is almost threefold than that of other professionals and technicians.

Even more interesting, not only a higher proportion of teachers have a secondary job, but also such share increased over the decade. During the same period the proportion of other professionals and technicians with secondary job decreased.

Table 3 shows the relative earnings at the main job of the groups being compared by observable characteristics. Earnings are computed as hourly earnings, measured in terms of purchasing power parity (PPP, US\$, 2000). Hourly earnings for each individual are computed dividing the monthly income by 4.3 times the number of hours worked in a week.<sup>3</sup> Average school teachers' hourly earnings circa 1997 have been set equal to 100 for each country (i.e., the average hourly earnings of both, pre-school and elementary teachers and high school teachers altogether).

It is shown in the table that, on average, for both periods pre-school and elementary teachers earn less than high school teachers; these in turn earn less than other professionals and technicians circa 1997 and slightly more circa 2007. However, it should be noted that pre-school and elementary teachers' earnings increased during the period of analysis while that of high-school teachers slightly dropped. The most notorious change in earnings can be seen among other professional and technicians. On average it dropped almost 25% in real terms which corresponds to almost 40% of average teachers' earnings circa 1997. This suggests, by now, that the gap closed due to a decrease in other professionals and technicians real acquisitive capacity.

Regarding differences according to the observable characteristics of the populations the typical patterns arise. Men earn more than women, especially in the case of other professionals

---

<sup>3</sup> The monthly income corresponds to the monthly earnings received from the main occupation in the month previous to the survey. The job schedule is captured with survey questions of the type, for example: "¿Quantas horas trabalhava normalmente por semana nesse trabalho? ¿Cuántas horas trabaja efectivamente en su empleo o actividad principal? Señale horas semanales, ¿cuántas horas efectivas al día trabajó la semana pasada? ¿Cuántas horas trabajó la semana pasada en la ocupación principal? El mes pasado, ¿cuántas horas a la semana trabajó en este negocio o empresa? ¿Cuántas horas por semana trabaja regularmente como...? ¿Cuántas horas, días y en qué jornada trabajo efectivamente la semana anterior?". So, it can be inferred that teachers are referring not only to their effective class time but to their whole job schedule (including preparation, grading, meeting times and the like).

and technicians. Earnings increase along a worker's life span, as well as with higher educational attainment. People that live with kids, live with elder people, are not household heads and live with another wage earner tend to earn less than those who don't or are not. These differences tend to be more pronounced among other professional and technicians than among teachers. Additionally, part-time workers and those who report having more than one job earn more than those who don't. The difference between workers who have a second job and those who don't slightly decreased during the decade, while the difference between those who are part-time workers and those who are not markedly increased.

At the aggregate, on average, other professionals and technicians earn around 81% and 23% more than pre-school and elementary teachers, circa 1997 and circa 2007 respectively. Also, they earn 21% more than high school teachers circa 1997, and 4% less circa 2007 (although this last difference is not significant at conventional levels). These statistics, however, are merely referential. They compare teachers with professionals and technicians that might substantially differ in terms of observable characteristics. As shown above in this section, teachers and other professionals and technicians differ regarding their human capital, job characteristics and socio-demographic composition. Then, it is appropriate to think that these differences in observable characteristics play a role explaining the earnings differentials. Hence, controlling the earnings gap by observable characteristics becomes necessary for a better estimation of the underlying earnings gap. The next section presents computations of the earnings gaps between teachers (preschool and primary, and secondary) and other professionals and technicians after matching individuals according to their observable characteristics.

### **3. Earnings Changes at the turn of the 20<sup>th</sup> Century for teachers vis-à-vis other professionals and technicians**

The extent to which the earnings differentials can be attributed to differences in observable characteristics is explored next. This is done using matching comparisons such that each teacher is paired with a professional or technician with the same observable characteristics (for methodological details see Ñopo, 2008). The characteristics are gender, age, education, presence of kids (12 or younger) in the household, presence of elders (65 or older) in the household, whether the workers is or not household head, presence of other wage earners in the household, whether the individual has a part-time work, and whether the individual holds a secondary job (all together will be referred as the “full set” of observable characteristics). These variables are sequentially added as matching variables and the results are reported in Figure 1. The decompositions are sequentially calculated for (i) pre-school and elementary teachers and (ii) high school teachers, for the first (circa 1997) and second (circa 2007) periods, vis-à-vis other professionals and technicians.

#### **3.1 Evolution of Average Earnings Gaps (controlling for observable characteristics)**

Figure 1 shows the drop in earnings gaps between the teaching groups and their comparing group of other professionals and technicians for the period under analysis (the panel “a” of the figure is for pre-school and elementary teachers and the panel “b” for high school teachers). All the earnings gaps are measured in terms of percentages of the average earnings of the teaching group that takes part on the comparison. The first pair of boxes, at the left, shows the earnings gap that is measured with no matching at all. The second pair of boxes shows the gap that remains after matching teachers and non-teachers on gender only. That is, each male teacher is compared to a male professional or technician and each female teacher to a female professional or

technician. Moving to the right each pair of boxes shows the gaps that remain after adding a matching variable. In this way, the last pair of boxes show the earnings gaps between teachers and other professionals and technicians that have the same observable characteristics on nine variables (gender, age, education, presence of children at home, presence of elders at home, an indicator for being a household head, an indicator for the presence of other income earner at home, part-time work and an indicator for holding more than one job). That is, when moving two boxes to the right on Figure 1 the comparison gets restricted to individuals with the same observable characteristics, adding one characteristic at a time.

The figure shows a drop in earnings gaps during the period that is more pronounced for pre-school and elementary teachers than for high school teachers. For the latter the drop in earnings gaps vis-à-vis other professionals and technicians is not statistically significant for almost all sets of matching characteristics.

Table 4 shows the same earnings gaps by country. Similarly to Figure 1, each pair of columns of the table corresponds to the earnings gap that remains after matching on a set of observable characteristics. Within each pair of columns, the first column corresponds to circa 1997 results and the second, circa 2007 results. The first pair of columns corresponds to the original earnings gap (the one that is measured with no matching at all). Moving to the right, each pair of columns add a matching variable such that in the last column of the table, teachers and other professionals and technicians being compared have the same observable characteristics on the nine variables.

Although some countries present negative original earnings gaps, unexplained earnings gaps after controlling for the full set of observable characteristics are either positive or statistically zero; these results provide evidence of notable cross-country heterogeneity behind the region averages reported in Figure 1. Looking at each country separately it can be seen that the original earnings gap between pre-school and elementary teachers vis-à-vis other professionals and technicians

decreased in most countries of the region but it did specially for Bolivia, Brazil and Dominican Republic. The only countries where such gap increased were Costa Rica and Ecuador. The gap regarding high school teachers markedly decreased for Bolivia, Brazil and Uruguay; the gap increased for Paraguay, Nicaragua and El Salvador. All in all, the original and unexplained earnings gaps dropped for both specifications of regions' average and for both pairs in comparison.

To what extent do the results obtained by matching differ from those obtained by earnings functions? As pointed out by Ñopo (2008) there should be no differences between the two approaches as long as the estimations are performed in the common supports of the distributions of observable characteristics. This is something that regularly remains overlooked with the traditional linear approach. Table A3 (see the on-line Appendix) shows earning gaps decompositions comparing the results obtained from a linear specification and matching. For the former the table shows the differences that arise on the decomposition when the common support is taken or not into account. As it is shown in the table, the results from matching and linear regressions restricted to the common support are very similar, differing only on the magnitude of the standard errors. The advantage of the matching approach, then, relies on the possibility of exploring not only the average gap but also (and more importantly) its distribution. This will be exploited in the next sub-section.

Before that let's turn to the question of what is behind the decrease in earnings gap reported here. The drops in unexplained earnings gaps can arise either as a result of a general trend of gaps decreasing in the segments considered of the labor markets (that is, those for professionals and technicians, where teachers are involved), or can also be the result of changes over time of the distribution of individuals' observable characteristics. To further explore the effects of labor market trends versus changes in labor markets composition, Table 5 presents a "matching after matching" exercise (Ñopo and Hoyos, 2010) disentangling both. The first stage of

matching is performed with the full set of observable characteristics, matching teachers with other professionals and technicians in both moments under consideration (circa 1997 and circa 2007), as it has already been performed. After that, the matching after matching exercise is performed for the two matched sets of workers, matching the circa 1997 data with the one from circa 2007. In this way not only teachers and non-teachers show no differences in observable characteristics, but also they show no changes in the distribution of those characteristics during the period under analysis. The results, shown in Table 5, indicate that there is more evidence of a general trend of decreasing gaps than one of an improvement of teachers' characteristics. The change in earnings gaps due to changes in the distributions of observable characteristics is positive and higher for pre-school and elementary teachers, but compensated by the change in the counterfactual component. Most of the change in gaps is due to an earnings contraction for other professionals and technicians during the period of analysis.

### **3.2 Changes in the Distribution of the Unexplained Earnings Gap**

After matching individuals on the basis of observable characteristics it is possible to explore not only the average but also the distribution of the earnings gaps in each period. In general, as reported in Mizala and Ñopo (2011), pre-school and elementary school teachers' underpayment is more pronounced among older and more educated workers, household heads, part-time workers, and those who report having more than one job. As reported in Table 5, during the period under analysis there is evidence of a general trend over all the labor markets for a reduction of earnings gaps. Within this matching exercise, nonetheless, it is possible to explore the segments of the labor markets for which the drops in gaps have been more pronounced. The bigger drops in earnings gaps for pre-school and elementary teachers occurred among younger individuals, those with higher education (secondary complete or more), with no elders at home, part-time workers

and those with no secondary jobs. For high school teachers, the earnings gaps are more pronounced among household heads and those holding more than one job. Among these teachers there is no particular segment of the market for which the gap dropped particularly more than the rest.<sup>4</sup>

Figure 2 shows the unexplained earnings gaps along the individuals' earnings distribution. The first panel of it shows the unexplained earnings gap that pre-school and elementary school face in comparison to other professionals and technicians; the second panel does it for high school teachers. Both show that the earnings gap between teachers and comparable workers in Latin America are driven by pay differences at the top percentiles of the earnings distribution. In this regard there is no much cross-country heterogeneity.<sup>5</sup>

This first panel of Figure 2 evidences that, after controlling by the full set of observable characteristics, there are no major differences in hourly earnings between pre-school and elementary teachers and other professional and technicians for the bottom third of the population circa 2007, but in the highest percentiles of the earnings distribution teachers earn less than comparable workers. The second panel depicts similar results, although high school teachers enjoy an earnings premium in the first percentiles of the earning distribution and smaller changes between circa 1997 and 2007.

### **3.3 Exploring the Role of Some Amenities: Schedules, Vacations, Secondary Jobs and Tenure**

“Typical policy discussions about the choice of a teaching career highlight the extra amenities that come with a teaching job. Two of the most salient of those amenities are the shorter (and flexible) job schedules, on the one hand, and the more stability that the profession

---

<sup>4</sup> Confidence intervals for the unexplained earnings gap between teachers and non-teachers by different characteristics, after controlling by the full set, can be found on Figures A1 and A2 of the on-line Appendix.

<sup>5</sup> Country-by-country results of the unexplained earnings gaps along percentiles of the earnings distribution are not shown here but these are available from the authors upon request.

enjoys, on the other. As it is typical in economics, these extra amenities have to come at a price. In this case such price would be expressed in terms of earnings disparities between teachers and their peers.” (Mizala and Ñopo, 2011). The shorter and flexible job schedules at the teaching profession imply, in turn, extra freedom for the possibility of holding a second job. As a matter of fact, in Table 2 we showed that while more than half of the teachers work part-time at their main job (30 hour per week or less) it is only around one-fifth of other professionals and technicians who do so. Not only that, but also the share of teachers who report having a secondary job is higher than that of other professionals and technicians, especially for those teaching at the high school level.

With these considerations we analyze the role of job schedules going beyond the measurement of earnings gaps in hourly terms. We explore earnings gaps as adjusted hourly earnings. These earnings are measured in terms of purchasing power parity (PPP, US\$ 2000) as well. Adjusted hourly earnings try to capture the fact that job-breaks are not the same across occupations, but since information about vacation periods is not available in the household surveys we built a proxy. Adjusted hourly earnings are computed as follows: for teachers, we assume a two-month paid vacation period so that teachers hourly earnings are multiplied by a 12/10 ratio; for other professionals and technicians dependent workers we assume a one-month paid vacation period so that hourly earnings are multiplied by a 12/11 ratio; and for independent workers we assume no paid vacations so that their monthly earnings are multiplied by 12/12=1. Paid vacations might vary across (and within) countries and over the life cycle, so this proxy is just a coarse approximation and should be taken only as a ballpark figure of the role of these amenities on the earnings gaps. Table 6 presents earnings gap decompositions for adjusted hourly earnings,

for pre-school and elementary school teachers and for high school teachers (in both cases, vis-à-vis other professionals and technicians).<sup>6</sup>

Next, we incorporate into the analysis an extra possibility that teachers enjoy regarding the use of their time, the holding of a second job. As highlighted in Table 2, teachers' propensity to have a second job is higher than that of other professionals and technicians, especially for those teaching at the high-school level (for this later group almost one in four teachers have a second job). This expands the income generation possibilities for teachers and may also be considered as an amenity linked to the profession. So we analyze next the earnings gaps in labor income for the main and secondary sources.

Many countries within our data report the existence of second jobs but only in six of them it is possible to obtain data for earnings, hours worked per week and type of activity in the second job: Bolivia, Brazil, Costa Rica, Ecuador, Nicaragua and Paraguay. The next part of the analysis will then focus on these countries. The sample drops dramatically as a result of two combined restrictions on the data. First, this sample of six countries approximately constitutes 75% of the observations that have been used for the previous results. Second, within the six countries we restrict attention to those individuals who: (i) hold a second job, (ii) have information on earnings, hours worked per week and type of activity in the second job; and (iii) the second job activity is within the professionals and technicians group (i.e. we discard those individuals whose second job is under the occupational categories of Legislators, Managers, Armed forces and, especially, Office workers, to be consistent with our previous estimates and our critique to the previous literature). Combining the two restrictions, the resulting sample represents around 8% of the original teachers sample circa 1997 and 10% circa 2007, 6% of the original non-teachers sample circa 1997

---

<sup>6</sup> For monthly earnings at the main occupation (i.e., the monthly value of hourly earnings), the decomposition shows that monthly earnings gaps are higher than the hourly earnings gaps previously reported in Table 4, both at their original measure and at the one that remains after controlling for the full set of observable characteristics. This comes as no surprise as teachers report working less hours per week than their counterparts at their main occupation. These results are not shown here but are available from the authors upon request.

and 4% circa 2007. Brazil becomes utterly representative, holding around 91% of the observations in both periods. Also, the share of household heads and (as expected) part-time workers is higher in this sub-sample in comparison to the original sample.<sup>7</sup>

Table 7 shows selected descriptive statistics for the sub-sample. The upper panel of the table (main job) depicts two important patterns that are in line with what was previously reported in Table 3. First, part-time workers at their main job earn more than those who are not, and a greater share of teachers report working part time. Second, to an important extent the drops in earnings gap at the main job are due to a drop in relative earnings for other professional and technicians. The intermediate panel of the table shows data from the second job. Two results emerge. First, to an important extent (with the exception of high school teachers circa 2007) the second job of teachers tends to be at another teaching position. Second, earnings gaps at second jobs did not change as much as they did for main jobs, and this is mainly a consequence of the relative improvement of other professionals and technicians' earnings during the period. The bottom panel of Table 7 shows descriptive statistics for main and secondary jobs combined (i.e., earnings are equal to the sum of main job and second job monthly earnings). The evidence still points towards a higher number of working hours, and higher earnings, for non-teachers than for teachers.

Table 8 shows the original and the unexplained earnings gap for main and secondary job (using hourly earnings), and the combination of both (using monthly earnings). Since we are restricting the sample to those workers that report having a second job, the "Full Set" specification does not include the "more than on job" variable. Additionally, we add another control variable: whether the worker's second job is related to school teaching or not after controlling by the full set of observable characteristics. The unexplained hourly earnings gaps at the second job are also

---

<sup>7</sup> These results are not reported here but available upon request.

positive but smaller than those at the main job for both periods. Both, the gaps at the main and second jobs decreased during the period but the drops are not statistically significant (perhaps due to the dramatic reduction in the sample size for this exercise with six countries and second job holders).

Adding the control for teaching activities at the second job does not change the unexplained earnings gaps (statistically speaking). Teachers in their second jobs, being those involved or not with teaching duties, face earnings gaps vis-à-vis other professionals and technicians. This may reflect the existence of some individuals' unobservable characteristics (or abilities) that the labor markets reward for which teachers fare worse than their peers. To further explore such possibility we estimate:

$$y_{ij} = \alpha + t_{ij}\beta + \mu_i + \varepsilon_{ij},$$

where:

$y_{ij}$  represents the logs of earnings of individual  $i$  in job  $j$ ;

$t_{ij}$  is a dummy variable that takes the value 0 if the individual  $i$  is a teacher in her/his job  $j$  and 1 if she/he works as other professional or technician at such job;

$\mu_i$  is the unobserved (job-independent) individual heterogeneity, and

$\varepsilon_{ij}$  is an idiosyncratic error term.

The model is estimated through fixed effects for each of the two available times (circa 1997 and circa 2007) separately. For each regression we use the matching weights such that differences in observable characteristics between teachers and other professionals and technicians (at least those using in the matching: gender, age, education, presence of children at home, presence of elders at home, an indicator for being a household head, an indicator for the presence of other income earner at home, part-time work and whether or not second job involves school teaching activities) are vanished. Table 9 shows the estimation results for the two periods.

Consistent with our finding of a reduction on the earnings gaps, the table reports that the “teaching penalty” ( $t$ ) dropped during the period. Figure 3 shows the empirical distributions of the unobserved individual heterogeneity term for different groups of individuals according to the type of job they hold at their main and secondary jobs. Due to the small sample size for this exercise we pooled the data from circa 1997 and circa 2007 for this plotting (after the estimation of the fixed-effects regressions). The unobserved heterogeneity among teachers is at the left of that for other professional and technicians, providing additional credence to the idea of such existence of some individuals’ unobservable characteristics (or abilities) that the labor markets rewards for which teachers fare worse than their peers.

The other amenity we explore in this sub-section is tenure. It has been typically claimed that the teaching profession entails more job stability than others. This may in turn convert into a compensating differential that teachers are willing to accept in the form of lower salaries. Next we assess the role of job tenure on the earnings gaps. Job tenure is defined here as the approximate number of years an individual has remained in the same job at the moment of the survey. As in the previous case with second jobs, this analysis cannot be performed for the thirteen countries of the original analysis. Data on job tenure is available in seven countries: Bolivia, Brazil, Honduras, Nicaragua, Panama, Paraguay and Uruguay. Restricting the data to these countries implies using 77% of the original data for teachers circa 1997 and 76% circa 2007; as well as 62% and 74% of the non-teachers’ group for circa 1997 and circa 2007 respectively. No descriptive statistic within this restricted data set is significantly different than those reported in Table 2 for the set of thirteen countries.

Table 10 shows the earnings gaps decompositions for pre-school and elementary school teachers and for high school teachers (vis-à-vis other professionals and technicians) using the current data subset, adding job tenure as a control variable. The earnings gap for preschool and

elementary teachers in both periods and for all specifications reduces when adding job tenure as a control variable. These results give credence to the idea that job stability acts as a compensating differential. For high school teachers the gap declines after adding job tenure as a control circa 2007; but circa 1997 it increases. These results suggest that job stability has higher intrinsic value nowadays. Table A4 (on-line Appendix) depicts similar results by country. These results, however, must be taken with caution due to the smaller sample size and (especially due to) the smaller size of the common support.

On this regard it is important to bring up another discussion, the earnings differences within the public and private sectors. We will see that not only a comparatively higher share of teachers work in the public sector, but that the differences regarding job stability within the sectors provide additional insights about how, if so, the job stability is a compensating differential.

### **3.4 Earnings differences within the public and private sectors**

Bolivia, Brazil, Costa Rica, Dominican Republic, El Salvador, Panama, Peru, Paraguay and Uruguay both periods' surveys report whether the individual holds a job in the public or private sector. This sample holds around 86% of the original teachers sample circa 1997 and circa 2007, and 71% of the original non-teachers sample circa 1997 and 87% circa 2007. Of this sample 81% of the teachers were working at the public sector circa 1997. Circa 2007 this share was 76%. Regarding other professionals and technicians, 38% and 24% worked in the public sector circa 1997 and circa 2007 respectively (Table 11).

Table 11 shows some descriptive statistics for teachers and other professionals and technicians split by job sector. As previously suggested, the earnings gap falls between circa 1997 and 2007 due to a comparatively larger fall in real earnings for other professionals and technicians compared to teachers. The gaps fell particularly for public sector pre-school and elementary

teachers. The job sector split shows other interesting results: Gender differences are driven by differences in the private sector, in which a comparatively higher share of men work in non-teaching occupations; fertility dropped particularly among public sector workers, however, public sector workers continue being more fertile which might explain the higher share of them reporting being household heads; part-time work increased for high school teachers and non-teachers working in the private sector. Tertiary education attainment increases for teachers working in the private sector, reversing the gap between teachers and other professionals and technicians in this regard.

Table 12 shows the earnings gaps decompositions for pre-school and elementary school teachers and for high school teachers (vis-à-vis other professionals and technicians) using the current data subset, adding whether the individual works in the public sector or not as a control variable. Adding this variable as a control slightly increases the earnings gap for preschool and elementary teachers in both periods and for all specifications; and it does so slightly more for high school teachers. Table A5 (in the on-line appendix) shows the results by country.

### **3.5 The differentiating role of job tenure between the public and private sectors:**

Those countries that report data on job sector and job tenure are: Bolivia, Brazil, Panama, Paraguay and Uruguay. Combining the two restrictions, the sample holds 71% of the original teachers sample circa 1997 and circa 2007, 46% of the original non-teachers sample circa 1997 and 71% circa 2007.

Figure 4 presents Kernel density estimations of job tenure for teachers and other professionals and technicians for the two years under analysis, split by job sector. It can be highlighted from that figure that, in fact, public teachers enjoy nowadays a positive tenure gap vis-à-vis other professional and technicians working in the public sector. Public Sector teachers

increased their average tenure (by 2.11 years for pre-school and elementary teachers and by 1 year for school teachers) and the public sector non-teaching group increased it (by 0.3 years). On the other hand, teachers in the private sector have less job stability than other professionals and technicians although the increase throughout the decade favored greatly teachers: private sector pre-school and primary teachers increased their average tenure by 1.3 years and high school teachers by 1.8 years. In contrast, non-teachers working in the private sector increased their average tenure just about 0.6 years. Such tendency of a widening tenure gap in favor of teachers goes in line with the fact that, as shown in Table 3, teachers became older during this period. As a matter of fact, average age increased, on the one hand, by 4.4 years for pre-school and elementary teachers and by 3.3 years for high school teachers; and on the other hand it only increased by 0.3 years for other professionals and technicians. All these inter-temporal average changes are statistically significant at the 1% level.

Figure 5 presents the non-parametric regressions of tenure on earnings. The figure shows that other professional and technicians earn more than teachers in both periods and such differences appear to increase with tenure. However, these differences are smaller in the private sector. These results hold for every country considered. Nevertheless, this analysis does not take into account the role of observable characteristics. For that reason, we perform a matching exercise that controls for differences in observable characteristics next.

Table 13 shows the earnings gaps decompositions for pre-school and elementary school teachers and for high school teachers (vis-à-vis other professionals and technicians) using the data subset restricted on individuals that report job sector and job tenure, adding job sector and job tenure as control variables. As previously found, adding job sector as a control variable increases the earnings gap in both periods and for all specifications, however, job tenure reduces it,

particularly nowadays. Table A6 (in the on-line appendix) shows the results by country. These results, however, must be interpreted with caution due to the small size of the common support.

#### **4. Conclusions**

This paper examines whether teachers' earnings in Latin America are similar to those of other professionals and technicians, and how these earnings gaps evolved between circa 1997 and circa 2007. Since the available empirical evidence has shown that the sign and magnitude of the conditional earnings differential between teachers and other workers depend crucially on the definition of the comparison group, we build upon the results of Mizala and Ñopo (2011) using the methodology developed in Ñopo (2008). This approach emphasizes earnings differences in the supports of the distributions of observable characteristics and provides insights into the distribution of unexplained pay differences, which nurtures our comparison between periods. Furthermore, using the matching after matching approach we were able to provide further insights on the change of the earnings gap during the decade under analysis.

The results show that teachers are underpaid vis-à-vis other professionals and technicians in Latin America in both periods: circa 1997 and circa 2007; although these gaps decreased through the decade. Nonetheless, there is an important cross-country heterogeneity behind the region averages. In particular, Brazil affects greatly the region averages due to its size. Despite this, the main conclusions hold if we include Brazil or not: High school teachers are more educated than other professionals and technicians but their years of education are not properly rewarded in the labor market. Working part-time is a characteristic that explains teachers' underpayment –pre-school and elementary school teachers enjoy greater flexibility in the work. Teachers' lower earnings are being compensated through lower effective labor in the main job, which not only

eases prospects of having a family but also eases the decision of having/finding a second job, accepting the possibility of lower (main job) earnings.

Although being able to work part-time is a major reason behind the decision of having a second job, it is important to further explore this possibility; in fact, a greater share of teachers report having a second job. We find that teachers are also being underpaid in their second job vis-à-vis other professionals and technicians, although these differences are smaller than in their main job, and also decreased throughout the decade. This calls for the role of some possible unobservable characteristics that differ between teachers and their peers and seem to be explaining part of the gap. Additionally, job stability has been found as another salient characteristic within the teaching profession, especially in the public sector. The returns to job tenure among teachers, however, were found to be smaller than those among other professionals and technicians. This adds elements to portray the picture of a teaching profession as a labor market option for individuals that tend to have lower aspirations, lower ability. Being that the case, the issue of selection into the teaching profession becomes especially relevant and calls for policy attention.

In general we found that the earnings gap decreased for each of the segments of the population provided by the control variables. Even more interesting, preschool and elementary teachers' earnings gap decreased importantly during the decade, especially for those who are females, younger and work part-time. Furthermore, in the hypothetical situation of no changes over time in the distribution of characteristics, results suggest an important decrease in the earnings gaps driven by the unexplained component of the gap, particularly for pre-school and elementary teachers. All in all, the analysis performed provides evidence that the wage gap

decreased during the ten year span of analysis, driven by the change in preschool and elementary teachers' underpayment throughout the time span and a decrease in non-teachers real income.

Moreover, important differences along the earnings distribution were found. Teachers in the highest percentiles of the earnings distribution earn less than other professionals and technicians, however, these earnings differences decreased throughout the decade. At the same time, teachers in the bottom percentiles (the bottom third of the population) have similar or higher earnings than comparable workers. This can be explained because in many countries teachers are rewarded through a single salary schedule which implies a salary structure much more compressed than the one of other professionals and technicians.

This salary structure is appealing to teachers as a fair way to compensate everyone, because it does not make distinctions that might disturb relationships among them. In this scheme equal pay is provided regardless of differing efforts and abilities; salaries are unrelated to the activities performed at the schools; being seniority and, to a lesser extent, the level of education the primary basis for any pay increase, which means that in the teaching profession loyalty rather than actual job performance is rewarded.

This system implies that the teaching profession probably attracts people with a preference for job stability and security, and at the same time equal pay regardless of performance penalizes the highly effective teachers who should be earning more. Thus, the single salary schedule might not be attractive to high performing teachers, especially in the public sector. For this reason, several countries are reforming traditional systems of recruiting teachers as well as mechanisms of paying and rewarding them, in order to attract and retain highly qualified individuals into teaching, and to get teachers to work hard to raise student learning (OECD, 2009).

	Definition	Average hourly earnings (purchasing power parity, US\$, 2000)* Circa 1997    Circa 2007		Definition	Average hourly earnings (purchasing power parity, US\$, 2000)* Circa 1997    Circa 2007		(as percentage of teachers' average earnings circa 1997 and circa 2007, respectively) Circa 1997    Circa 2007	
Psacharopoulos et al. (1996).	School and university teachers. The definition included other school staff in cases when disaggregation was not possible.	5.45	5.87	Public and private sector employees, excluding domestic servants and agricultural workers.	3.53	3.17	-35.3%	-46.0%
Liang (1999)	Preschool, special education, primary and secondary teachers; those employed in the formal sector –working more than 20 hours per week, not currently studying.†	5.16**	5.17**	Workers employed in the formal sector –working more than 20 hours per week, not currently studying.	3.78**	3.15**	-26.7%**	-39.1%**
Hernani-Limarino (2005)	Preschool, primary, and secondary teachers.‡	5.06	5.29	Three alternative definitions: i) All workers ii) All workers that have at least completed secondary education iii) All workers that are identified either as office workers or professionals/technicians	i) 3.71    3.20 ii) 6.50    4.42 iii) 5.11    4.44		i) -26.6%    -39.6% ii) 28.4%    -16.3% iii) 0.9%    -16.0%	
<b>Mizala and Nopo (this document)</b>	School teachers excluding those with particular specialties (e.g., teachers for students with special needs, language instructors, sports instructors, and dance or art instructors)	5.06	5.29	Those workers classified as "professionals" and "technicians and associate professionals" according to the occupational codes in country-year each survey.	8.32	6.32	64.4%	19.4%

† In Liang (1999), some university teachers are also selected by the author since his data does not permit a breakdown of different categories of teachers for El Salvador and Venezuela.

‡ In Hernani-Limarino (2005), for the cases of Argentina, Colombia, and Mexico, the author also included those working in special, technical, or higher education.

\* Average hourly earnings for all comparisons are computed using the data set for this document, but the teachers and comparison group definitions of the different authors. In the case of Liang (1999), our data does permit a breakdown of different categories of teachers in El Salvador, so university teachers are not included. Earnings gaps are not being controlled by any observable characteristic.

\*\* Ecuador and Bolivia are not included since our data does not report whether the individual is studying or not at the moment of the survey.
